Meeting 16: Axiomatic

BOOLE ORDERS LUNCH

NO, NO, YES, NO, NO, YES, YES, NO, NO, NO, YES...
Announcements

- Homework 4 due next Friday at 6:00pm
- Talk (with me, with the class in office hours, on Piazza) about your course project ideas

Homework 3 Comments

- "I like the way that things tend to build upon each other in this course, and that with each new homework I tend to learn something new about, or that better contextualizes, a previous homework. I would say that I would change the level of effort just to get a baseline going for the homeworks. I tend to find that I am not able to understand how to even approach the more interesting problems (e.g. while), until the last few days before the homework is due."
Assignment #4:
Program Verification and Implementation

CSCI 5535 / ECEN 5533: Fundamentals of Programming Languages

Spring 2018: Due Friday, March 23, 2018

This homework has two parts. The first considers a deductive system for thinking about program correctness. The second considers a semantics that is closer a machine implementation.

1 Axiomatic Semantics: IMP

We continue to consider the same language IMP with the syntax chart:

<table>
<thead>
<tr>
<th>Typ</th>
<th>τ ::=</th>
<th>num</th>
<th>num</th>
<th>numbers</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>bool</td>
<td>bool</td>
<td></td>
<td>booleans</td>
</tr>
<tr>
<td>Exp</td>
<td>e ::=</td>
<td>addr[a]</td>
<td>a</td>
<td>addresses (or “assignables”)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>num[n]</td>
<td>n</td>
<td>numeral</td>
</tr>
<tr>
<td></td>
<td></td>
<td>bool[b]</td>
<td>b</td>
<td>boolean</td>
</tr>
<tr>
<td></td>
<td></td>
<td>plus(e₁;e₂)</td>
<td>e₁ + e₂</td>
<td>addition</td>
</tr>
<tr>
<td></td>
<td></td>
<td>times(e₁;e₂)</td>
<td>e₁ * e₂</td>
<td>multiplication</td>
</tr>
<tr>
<td></td>
<td></td>
<td>eq(e₁;e₂)</td>
<td>e₁ == e₂</td>
<td>equal</td>
</tr>
<tr>
<td></td>
<td></td>
<td>le(e₁;e₂)</td>
<td>e₁ &lt;= e₂</td>
<td>less-than-or-equal</td>
</tr>
<tr>
<td></td>
<td></td>
<td>not(e₁)</td>
<td>!e₁</td>
<td>negation</td>
</tr>
<tr>
<td></td>
<td></td>
<td>and(e₁;e₂)</td>
<td>e₁ &amp;&amp; e₂</td>
<td>conjunction</td>
</tr>
<tr>
<td></td>
<td></td>
<td>or(e₁;e₂)</td>
<td>e₁</td>
<td></td>
</tr>
<tr>
<td>Cmd</td>
<td>c ::=</td>
<td>set<a href="e">a</a></td>
<td>a := e</td>
<td>assignment</td>
</tr>
<tr>
<td></td>
<td></td>
<td>skip</td>
<td>skip</td>
<td>skip</td>
</tr>
<tr>
<td></td>
<td></td>
<td>seq(c₁;c₂)</td>
<td>c₁; c₂</td>
<td>sequencing</td>
</tr>
<tr>
<td></td>
<td></td>
<td>if(e;c₁;c₂)</td>
<td>if e then c₁ else c₂</td>
<td>conditional</td>
</tr>
<tr>
<td></td>
<td></td>
<td>while(e;c₁)</td>
<td>while e do c₁</td>
<td>looping</td>
</tr>
</tbody>
</table>

Addr  a

As before, addresses a represent static memory store locations and are drawn from some unbounded set Addr and all memory locations only store numbers. A store σ is thus a mapping from addresses to numbers, written as follows:

\[ \text{Store } \sigma ::= \cdot \mid \sigma, a \mapsto n \]

The semantics of IMP is as a formalized as before operationally, and we consider the Hoare rules for partial correctness as in Chapter 6 of FSPL.
1.1. **Program Correctness.** Prove using Hoare rules the following property: if we start the command \( \text{while } e \text{ do } a := a + 2 \) in a state that satisfies the assertion \( \text{even}(a) \), then it terminates in a state satisfying \( \text{even}(a) \). That is, prove the following judgment:

\[
\{ \text{even}(a) \} \text{ while } e \text{ do } a := a + 2 \{ \text{even}(a) \}
\]

Hint: your proof should *not* use induction.

1.2. **Hoare Rules.** Consider an extension to IMP

\[
c ::= \text{do}(c_1 ; e) \text{ do } c_1 \text{ while } e \text{ at-least-once looping}
\]

with a command for at-least-once looping. Extend the Hoare judgment form \( \{ A \} c \{ B \} \) for this command.

## 2 Abstract Machines and Control Flow

In this section, we will consider a new implementation of language PCF based on abstract machines (i.e., K from Chapter 28 of PFPL).

One aspect of a structural small-step operational semantics (as we used in previous assignments) that seems wasteful from an implementation perspective is that we “forget” where we are reducing at each step. An abstract machine semantics makes explicit the “program counter” in its state.

2.1. Give a specification for K as a call-by-value language. That is, modify the definition of the judgments \( f \text{ frame} \) and \( s \rightsquigarrow s' \) from Section 28.1 of PFPL. You will also need to update the auxiliary frame-typing judgment \( f : \tau \rightsquigarrow \tau' \) from Section 28.2 in order to state safety.

2.2. **Safety.**

(a) Prove preservation: if \( s \text{ ok} \) and \( s \rightsquigarrow s' \), then \( s' \text{ ok} \).

(b) Prove progress: if \( s \text{ ok} \), then either \( s \text{ final} \) or \( s \rightsquigarrow s' \) for some state \( s' \).

2.3. **Implementation.**

(a) Implement call-by-value K. You need not include previously implemented language features (though you may include some of them if you want).

First, we have some new syntactic forms:

frames \( f \text{ type frame} \)
stacks \( k \text{ type stack = frame list} \)
states \( s \text{ type state = Eval of stack * exp | Ret of stack * exp} \)

Then, we will implement functions that define both the static and dynamic semantics
of the language.

\[
\begin{align*}
[e/x]e & \quad \text{val subst : exp -> var -> exp -> exp} \\
e \text{val} & \quad \text{val is_val : exp -> bool} \\
\Gamma \vdash e : \tau & \quad \text{val exp_typ : typctx -> exp -> typ option} \\
s \mapsto s' & \quad \text{val step : state -> state} \\
s \text{final} & \quad \text{val is_final : state -> bool} \\
k \mapsto \tau & \quad \text{val stack_type : stack -> typ option} \\
f : \tau \mapsto \tau' & \quad \text{val frame_type : frame -> typ -> typ option} \\
s \text{ok} & \quad \text{val is_ok : state -> bool} \\
s \mapsto_{\text{ok}} s' & \quad \text{val steps_pap : state -> state}
\end{align*}
\]

The \( s \mapsto_{\text{ok}} s' \) is the analogous iterate-step-with-preservation-and-progress for states.

\[
\begin{array}{c|c}
\text{s ok} & \text{s final} \\
\hline
\text{s \mapsto_{\text{ok}} s} & \text{s \mapsto s'} & s' \mapsto_{\text{ok}} s'' \\
\end{array}
\]

(b) **Extra credit: Exceptions.** Extend your \( K \) machine with exceptions as in Section 29.2. You may choose \( \text{nat} \) for the type of the value carried by the exception.

(c) **Extra credit: Continuations.** Extend your \( K \) machine with continuations as in Section 30.2. Implementing continuations is independent of implementing exceptions, so you may choose to do either or both. (Technically, you can encode exceptions with continuations.)

## 3 Final Project Preparation: Proposal Revision

### 3.1 Reading Papers

Follow some citations based on the papers you chose in Homework 2 and read in Homework 3. List at least three cited papers that seems relevant to follow up on. Include a citation along with a URL for each paper. For each of the additional papers, and for each question below, write two concise sentences:

(a) Why did you select this cited paper?

(b) What is the relation between the “main idea” of this cited paper and the “main idea” of the paper that cites it? You may want to skim the introductory and concluding bits of the cited paper along with the related work in the citing paper.

### 3.2 Proposal

Finalize your class project plan. Write an updated explanation of your plan (expanding and revising as necessary), and what you hope to accomplish with your project by the end of the semester. That is, on what artifact do you want to be graded?

Here are questions that you should address in your project proposal.

(a) Define the problem that you will solve as concretely as possible. Provide a scope of expected and potential results. Give a few example programs that exhibit the problem that you are trying to solve.

(b) What is the general approach that you intend to use to solve the problem?
(c) Why do you think that approach will solve the problem? What resources (papers, book chapters, etc.) do you plan to base your solution on? Is there one in particular that you plan to follow? What about your solution will be similar? What will be different?

(d) How do you plan to demonstrate your idea?

(e) How will you evaluate your idea? What will be the measurement for success?

4 Feedback and Discussion

4.1. Assignment Feedback. Complete the survey on the linked from the moodle after completing this assignment. Any non-empty answer will receive full credit for this part.

4.2. Assignment Discussion. Remember to sign up for a discussion session with your grader once you have received written feedback on your assignment. Engaging in a discussion session will receive full credit for this part.
Assignment #3:  
Compilation and Interpretation 

CSCI 5535 / ECEN 5533: Fundamentals of Programming Languages

Spring 2018: Due Friday, March 9, 2018

This homework has two parts. The first asks you to consider the relationship between a denotational formalization and an operational one. The second asks you to extend your language implementation in OCaml to further gain experience translating formalization to implementation.

1 Denotational Semantics: IMP

Recall the syntax chart for IMP:

| Typ  τ ::= | num num numbers | bool bool booleans |
| Exp e ::= | addr[a] a addresses (or “assignables”) | num[n] n numeral |
|           | bool[b] b boolean | plus(e₁;e₂) e₁ + e₂ addition |
|           |                   | times(e₁;e₂) e₁ * e₂ multiplication |
|           |                   | eq(e₁;e₂) e₁ == e₂ equal |
|           |                   | le(e₁;e₂) e₁ <= e₂ less-than-or-equal |
|           |                   | not(e₁) !e₁ negation |
|           |                   | and(e₁;e₂) e₁ && e₂ conjunction |
|           |                   | or(e₁;e₂) e₁ || e₂ disjunction |
| Cmd c ::= | set[a](e) a := e assignment |
|           | skip skip skip |
|           | seq(c₁;c₂) c₁;c₂ sequencing |
|           | if(e;c₁;c₂) if e then c₁ else c₂ conditional |
|           | while(e;c₁) while e do c₁ looping |

Addr a

As before, addresses a represent static memory store locations and are drawn from some unbounded set Addr and all memory locations only store numbers. A store σ is thus a mapping from addresses to numbers, written as follows:

\[ \text{Store } \sigma ::= \cdot | \sigma, a \mapsto n \]
The semantics of **IMP** is as a formalized in the previous assignment operationally. In this section, we will consider a denotational formalization.

The set of values **Val** are the disjoint union of numbers and booleans:

\[ \text{Val} \; \nu ::= \text{num}[n] \mid \text{bool}[b] . \]

1.1. (a) Formalize the dynamics of **IMP** as two denotational functions.

\[ [\cdot ] : \text{Exp} \rightarrow (\text{Store} \rightarrow \text{Val}) \]

\[ [\cdot ] : \text{Cmd} \rightarrow (\text{Store} \rightarrow \text{Store}) \]

(b) Prove that your denotational definitions coincide with your operational ones.

i. State the lemma that your definitions for expressions coincide.

ii. Prove the equivalence of your definitions for commands, that is,

\[ (\sigma, \sigma') \in [c] \text{ if and only if } \langle c, \sigma \rangle \Downarrow \sigma' . \]

Begin by copying your definition of \( \langle c, \sigma \rangle \Downarrow \sigma' \) from your previous homework submission.

1.2. **Manual Program Verification.** Prove the following statement about the denotational semantics of **IMP**.

If \( \text{while } e \text{ do } a := a + 2 \) \( \sigma = \sigma' \) such that \( \text{even}(\sigma(a)) \), then \( \text{even}(\sigma'(a)) \)

Unlike in the previous assignment, this time you should use your denotational semantics for the proof. **Hint:** your proof should proceed by mathematical induction.

## 2 Comparing Operational and Denotational Semantics

Regular expressions are commonly used as abstractions for string matching. Here is an abstract syntax for regular expressions:

\[
\begin{align*}
r & ::= \text{‘} c \text{‘} \quad \text{singleton – matches the character } c \\
| & \quad \text{empty} \quad \text{skip – matches the empty string} \\
| & \quad r_1 \; r_2 \quad \text{concatenation – matches } r_1 \text{ followed by } r_2 \\
| & \quad r_1 \mid r_2 \quad \text{or – matches } r_1 \text{ or } r_2 \\
| & \quad r^* \quad \text{Kleene star – matches 0 or more occurrences of } r \\
| & \quad . \quad \text{matches any single character} \\
| & \quad [\text{‘} c_1 \text{‘} \mid \text{‘} c_2 \text{‘}] \quad \text{matches any character between } c_1 \text{ and } c_2 \text{ inclusive} \\
| & \quad r+ \quad \text{matches 1 or more occurrences of } r \\
| & \quad r? \quad \text{matches 0 or 1 occurrence of } r 
\end{align*}
\]

We will call the first five cases the *primary* forms of regular expressions. The last four cases can be defined in terms of the first five. We also give an abstract grammar for strings (modeled as lists of characters):

\[
\begin{align*}
s & ::= \cdot \quad \text{empty string} \\
| & \quad cs \quad \text{string with first character } c \text{ and other characters } s
\end{align*}
\]
We write “by” as shorthand for bye.

We introduce the following big-step operational semantics judgment for regular expression matching:

\[ r \text{ matches } s \text{ leaving } s' \]

The interpretation of the judgment is that the regular expression \( r \) matches some prefix of the string \( s \), leaving the suffix \( s' \) unmatched. If \( s' = \cdot \), then \( r \) matched \( s \) exactly. For example,

\[ \text{‘h’} \text{‘e’}^+ \text{matches “hello” leaving “llo”} \]

Note that this operational semantics may be considered non-deterministic because we expect to be able to derive all three of the following:

\[ (\text{‘h’} | \text{‘e’})^* \text{matches “hello” leaving “hello”} \]
\[ (\text{‘h’} | \text{‘e’})^* \text{matches “hello” leaving “ello”} \]
\[ (\text{‘h’} | \text{‘e’})^* \text{matches “hello” leaving “llo”} \]

We leave the rules of inference defining this judgment unspecified. You may consider giving this set of inference rules an optional exercise.

Instead, we will use denotational semantics to model the fact that a regular expression can match a string leaving many possible suffixes. Let \( \text{Str} \) be the set of all strings, let \( \wp(\text{Str}) \) be the powerset of \( \text{Str} \), and let \( \text{RE} \) range over regular expressions. We introduce a semantic function:

\[ [\cdot] : \text{RE} \rightarrow (\text{Str} \rightarrow \wp(\text{Str})) \]

The interpretation is that \( [r] \) is a function that takes in a string-to-be-matched and returns a set of suffixes. We might intuitively define \( [\cdot] \) as follows:

\[ [r] = \lambda s. \{ s' \mid r \text{ matches } s \text{ leaving } s' \} \]

In general, however, one should not define the denotational semantics in terms of the operational semantics. Here are two correct semantic functions:

\[ [\text{'c'}] \overset{\text{def}}{=} \lambda s. \{ s' \mid s = \text{'c'} :: s' \} \]
\[ [\text{empty}] \overset{\text{def}}{=} \lambda s. \{ s \} \]

2.1. Give the denotational semantics functions for the other three primal regular expressions. Your semantics functions may not reference the operational semantics.

2.2. We want to update our operational semantics for regular expressions to capture multiple suffixes. We want our new operational semantics to be deterministic—it should give the same answer as the denotational semantics above. We introduce a new judgment as follows:

\[ r \text{ matches } s \text{ leaving } S \]

where \( S \) is a meta-variable for a set of strings. And use rules of inference like the following:

\[ \text{'c'} \text{ matches } s \text{ leaving } \{ s' \mid s = \text{'c'} :: s' \} \quad \text{empty matches } s \text{ leaving } \{ s \} \]

\[ r_1 \text{ matches } s \text{ leaving } S_1 \quad r_2 \text{ matches } s \text{ leaving } S_2 \]

\[ r_1 \mid r_2 \text{ matches } s \text{ leaving } S_1 \cup S_2 \]

Do one of the following:
\[ r \cdot r_{\text{red}} \triangleq \lambda s. \bigcup_{s' \in r_{\text{red}}(s)} \bigcup_{d \in Br_{r}(d_{s})} \]

\[ \Gamma_{r} l_{r} \triangleq \lambda s. \Gamma_{r}d_{s} \cup \Gamma_{r_{\text{red}}}s \]

\[ \Gamma_{r} r_{\text{red}} ? \quad r_{\text{red}}^{*} = \text{empty} \mid r_{\text{red}}^{+} \]

\[ K : \Delta E \rightarrow \text{Nat} \rightarrow (\text{Str} \rightarrow \mathcal{P}(\text{Str})) \]

\[ K_{r} 0 \triangleq \lambda s. \exists \]

\[ K_{r} k+1 \triangleq \lambda s. \exists s' \bigcup_{s' \in \Gamma_{r}(k)} \bigcup_{d \in Br_{r}(d_{s})} \]

\[ \Gamma_{r}^{*} \triangleq \lambda s. \bigcup_{k \in \text{Nat}} K_{r}(k)(s) \]
• *Either* give operational semantics rules of inference for \( r^* \) and \( r_1 r_2 \). Your operational semantics rules may *not* reference the denotational semantics. You may *not* place a derivation inside a set constructor, as in: \( \{ s \mid \exists S. r \text{ matches } s \text{ leaving } S \} \). Each inference rule must have a finite and fixed set of hypotheses.

• *Or* argue in one or two sentences that it cannot be done correctly in the given framework. Back up your argument by presenting two attempted but “wrong” rules of inference and show that each one is either unsound or incomplete with respect to our intuitive notion of regular expression matching.

Part of doing research in any area is getting stuck. When you get stuck, you must be able to recognize whether “you are just missing something” or “the problem is actually impossible.”

### 3 Implementation: General Recursion and Polymorphism

In this section, we will reformulate language ETPS so that it admits general recursion (and thus non-terminating programs) and parametric polymorphism.

Follow the “Translating a Language to OCaml” guidance from the previous homework assignment. That is, we will implement functions that define both the static and dynamic semantics of the language.

\[
\begin{align*}
[e'/x]e & \quad \text{val subst: exp -> var -> exp -> exp} \\
e & \quad \text{val is_val: exp -> bool} \\
\Gamma \vdash e : \tau & \quad \text{val exp_typ: typctx -> exp -> typ option} \\
e \mapsto e' & \quad \text{val step: exp -> exp} \\
\Gamma \vdash e : \tau & \quad \text{val steps_pap: typ -> exp -> exp}
\end{align*}
\]

To avoid redundancy in the assignment, you may skip implementing the big-step evaluator \( e \Downarrow e' \) in this assignment.

3.1. Adapt your language ETPS with general recursion. That is, replace the language T portion (primitive recursion with natural numbers) with language PCF from Chapter 19 of PFPL (general recursion with natural numbers).

3.2. Add recursive types (i.e., language FPC from Chapter 20 of PFPL). While type nat of natural numbers is definable in FPC, leave the primitive nat in for convenience in testing.

3.3. Add parametric polymorphism (i.e., System F from Chapter 16 of PFPL). Note that System F extends the typing judgment with an additional context for type variables:

\[
\Delta ::= \cdot \mid \Delta, t \text{ type} \\
t \quad \text{type variables}
\]
\[ r_1 \text{ matches } s \text{ leaving } S \]
\[ \cup \exists S' \ r_2 \text{ matches } s' \text{ leaving } S' \]
\[ r_1, r_2 \text{ matches } s \text{ leaving } \]
and a well-formedness judgment for types $\Delta \vdash \tau$ type. We thus have to update our implementation accordingly:

\[
\begin{align*}
  t & \quad \text{type typvar = string} \\
  \Delta & \quad \text{type kindctx} \\
  \Delta \Gamma \vdash e : \tau & \quad \text{val exp_typ : kindctx -> typctx -> exp -> typ option} \\
  \Delta \vdash \tau \text{ type} & \quad \text{val typ_form : kindctx -> typ -> bool}
\end{align*}
\]

Explain your testing strategy and justify that your test cases attempt to cover your code as thoroughly as possible (e.g., they attempt to cover different execution paths of your implementation with each test). Write this explanation as comments alongside your test code.

4 Final Project: Proposal

4.1. Reading Papers. Continue reading the papers that you chose in Homework 2. For each of the five papers, and for each question below, write two concise sentences:

(a) Why did you select this paper?

(b) What is the “main idea” of the paper?

(c) How well is this main idea communicated to you when you read the first two sections and conclusion of paper, and skimmed the rest? In particular, explain what aspects seem important, are which are clear versus unclear. You may want to read deeper into the details of the paper body if these beginning and ending sections do not make the main ideas clear; make a note if this is required. 

Take a look at Keshav’s “How to Read a Paper” for further advice on reading papers.

4.2. Proposal. Continue thinking about your class project. Write an updated explanation of your plan (expanding and revising as necessary), and what you hope to accomplish with your project by the end of the semester. That is, on what artifact do you want to be graded? By writing your plan now, you are also generating a draft of part of your final report.

Here are questions that you should address in your project proposal. You will have the opportunity to revise your proposal in the next assignment, but the more concrete your proposal is early on, the better the feedback you are likely to receive.

(a) Define the problem that you will solve as concretely as possible. Provide a scope of expected and potential results. Give a few example programs that exhibit the problem that you are trying to solve.

(b) What is the general approach that you intend to use to solve the problem?

(c) Why do you think that approach will solve the problem? What resources (papers, book chapters, etc.) do you plan to base your solution on? Is there one in particular that you plan to follow? What about your solution will be similar? What will be different?

(d) How do you plan to demonstrate your idea?

(e) How will you evaluate your idea? What will be the measurement for success?
